Demand and Supply Analysis

Understanding the fundamentals of demand and supply is crucial for mastering microeconomics. This section breaks down the core concepts, including the law of demand and law of supply, determinants of demand and supply, and shifts versus movements along the curves.

Law of Demand

The law of demand states that, *ceteris paribus*, as the price of a good decreases, the quantity demanded increases, and vice versa. This negative relationship is represented by a downward-sloping demand curve. Factors affecting demand include income, preferences, prices of related goods, expectations, and number of buyers.

Law of Supply

The law of supply indicates that, all else equal, as the price of a good rises, the quantity supplied increases. This positive relationship produces an upward-sloping supply curve. Supply is influenced by production costs, technology, prices of related goods, expectations, and the number of sellers.

Shifts vs. Movements

It is important to distinguish between movements along curves and shifts of curves. A change in price causes movement along the demand or supply curve, while changes in non-price determinants shift the entire curve either left or right.

- Movement along demand/supply curve: caused by price changes
- Shift of demand/supply curve: caused by factors like income, preferences, or input prices

Market Equilibrium and Price Determination

Market equilibrium occurs where the quantity demanded equals the quantity supplied, determining the equilibrium price and quantity. This section focuses on how equilibrium is established and the effects of shifts in demand and supply.

Equilibrium Price and Quantity

The equilibrium price is the price at which the intentions of buyers and sellers match, resulting in no surplus or shortage. At this point, the market clears efficiently, and resources are allocated optimally.

Surplus and Shortage

When the price is above equilibrium, a surplus arises, causing sellers to lower prices. Conversely, a price below equilibrium creates a shortage, prompting prices to increase. These market forces push the price toward equilibrium.

Effects of Shifts in Demand and Supply

Changes in demand or supply conditions shift the respective curves, leading to new equilibrium prices and quantities. For example, an increase in demand raises both the equilibrium price and quantity, while an increase in supply lowers price and raises quantity.

Elasticity Concepts

Elasticity measures responsiveness of quantity demanded or supplied to changes in price or other variables. It is a key concept in understanding consumer behavior and market dynamics.

Price Elasticity of Demand (PED)

Price elasticity of demand quantifies the percentage change in quantity demanded resulting from a one percent change in price. It is calculated as:

$$PED = (\% \text{ change in quantity demanded}) / (\% \text{ change in price})$$

Demand is elastic if $|PED| > 1$, inelastic if $|PED| < 1$, and unit elastic if $|PED| = 1$.

Cross-Price Elasticity of Demand

This measures how quantity demanded of one good responds to a price change in another good. Positive cross-price elasticity indicates substitute goods, while negative values indicate complements.

Income Elasticity of Demand

Income elasticity shows how demand changes with consumer income variations. Positive income elasticity signifies normal goods, whereas negative signifies inferior goods.

Price Elasticity of Supply (PES)

PES measures responsiveness of quantity supplied to price changes. Factors influencing PES include production time, availability of inputs, and flexibility of producers.

Production and Cost Theory

This section covers the relationship between inputs and outputs in production, as well as cost structures firms face in the short and long run. Understanding these concepts is essential for analyzing firm behavior.

Production Functions

A production function expresses the maximum output attainable from given inputs. The concepts of total product, marginal product, and average product describe output changes as input levels vary.

Law of Diminishing Returns

This law states that as additional units of a variable input are added to fixed inputs, the marginal product eventually declines, holding other factors constant.

Cost Curves

Firms encounter various costs including fixed costs, variable costs, total costs, average costs, and

marginal costs. In the short run, some costs are fixed, while in the long run all costs are variable.

- **Fixed Costs (FC):** Costs that do not vary with output
- **Variable Costs (VC):** Costs that vary with output
- **Total Cost (TC):** $FC + VC$
- **Average Cost (AC):** TC divided by quantity produced
- **Marginal Cost (MC):** Cost of producing one additional unit

Market Structures

Market structures define the competitive environment in which firms operate. This section explores perfect competition, monopoly, monopolistic competition, and oligopoly with their defining characteristics and outcomes.

Perfect Competition

In perfect competition, many firms sell identical products, and no single firm can influence market price. Firms are price takers, and long-run profits tend to zero due to free entry and exit.

Monopoly

A monopoly exists when a single firm controls the entire market supply with no close substitutes. Monopolists set prices above marginal cost, leading to higher profits but potential inefficiencies.

Monopolistic Competition

This market features many firms selling differentiated products. Firms have some pricing power but face competition from similar products. In the long run, economic profits are zero.

Oligopoly

Oligopoly consists of few large firms dominating the market. Firms may engage in strategic behavior, collusion, or competition. Models such as Cournot and Bertrand explain oligopolistic interactions.

Consumer Choice and Utility

Consumer theory examines how individuals allocate their limited income to maximize satisfaction, or utility. This section reviews key concepts such as utility functions, budget constraints, and indifference curves.

Utility and Marginal Utility

Utility represents satisfaction derived from consuming goods and services. Marginal utility measures additional satisfaction from consuming one more unit of a good. Consumers aim to maximize total utility.

Budget Constraint

The budget constraint reflects all possible combinations of goods a consumer can afford given their income and prices. It is represented by a downward-sloping line on a graph with quantities of two goods.

Indifference Curves

Indifference curves represent combinations of goods providing the same level of utility. They are downward sloping and convex to the origin, showing diminishing marginal rates of substitution.

1. Consumers maximize utility where the budget line is tangent to an indifference curve.
2. This tangency condition implies equal marginal utility per dollar spent on each good.
