Overview of Radiation Therapy

Radiation therapy is a critical component of cancer treatment, utilizing high-energy radiation to target and destroy cancer cells while minimizing damage to surrounding healthy tissue. It can be used as a standalone treatment or in conjunction with surgery and chemotherapy. Understanding the principles of radiation therapy is vital for any healthcare professional involved in oncology.

Types of Radiation Therapy

There are several types of radiation therapy used in clinical practice:

1. **External Beam Radiation Therapy (EBRT):** This method delivers targeted radiation from outside the body. It is the most common form of radiation therapy.
2. **Brachytherapy:** This involves placing radioactive sources directly into or near the tumor, allowing for a high dose of radiation to the tumor while sparing surrounding tissues.
3. **Stereotactic Radiosurgery (SRS):** A non-surgical radiation therapy that precisely targets tumors in the brain or spinal cord using focused beams of radiation.
4. **Stereotactic Body Radiotherapy (SBRT):** Similar to SRS, but used for tumors located outside the brain, like those in the lungs or liver.
5. **Systemic Radiation Therapy:** Involves the administration of radioactive substances that travel through the bloodstream to target cancer cells throughout the body.
