Understanding Displacement and Velocity

Displacement and velocity are fundamental concepts in physics that describe motion. Displacement refers to the change in position of an object from its initial point to its final point, taking direction into account. It is a vector quantity, meaning it has both magnitude and direction. Velocity, on the other hand, describes the rate at which an object changes its position, also a vector quantity, indicating both speed and direction of motion.

Definition of Displacement

Displacement is defined as the shortest distance between the initial and final positions of an object, measured along a straight line. It is different from distance, which accounts for the total path length traveled regardless of direction. Displacement can be positive, negative, or zero depending on the chosen reference frame and direction.

Definition of Velocity

Velocity is the rate of change of displacement with respect to time. It is mathematically expressed as

velocity = displacement / time interval. Velocity indicates the speed of an object in a specific direction, distinguishing it from speed, which is scalar and lacks directional information. Instantaneous velocity refers to the velocity at a particular moment, whereas average velocity is calculated over a time interval.

Components of a Displacement Velocity Worksheet

Sample Problems and Solutions Explained

This section illustrates typical displacement velocity worksheet problems accompanied by detailed answer explanations to demonstrate how learners can approach and solve them effectively.

Example 1: Calculating Displacement

Problem: An object moves 5 meters east, then 3 meters west. What is its displacement?

Solution: Since displacement is vector quantity, consider directions: east as positive and west as negative.

$$1. \text{ Displacement} = 5 \text{ m (east)} + (-3 \text{ m (west)}) = 2 \text{ m east.}$$

The object's displacement is 2 meters to the east.

Example 2: Finding Average Velocity

Problem: A runner covers 100 meters north in 20 seconds. Calculate the average velocity.

Solution: Average velocity = displacement / time = $100 \text{ m} / 20 \text{ s} = 5 \text{ m/s north.}$

The average velocity of the runner is 5 meters per second directed northward.

Example 3: Interpreting Velocity-Time Graphs

Problem: Given a velocity-time graph showing constant velocity of 10 m/s for 5 seconds, find the

displacement.

Solution: Displacement = velocity $\times$ time = $10 \text{ m/s} \times 5 \text{ s} = 50 \text{ meters}$.

The object's displacement over 5 seconds is 50 meters in the direction of velocity.
