Understanding Complex Numbers and Their Division

Complex numbers combine a real part and an imaginary part, typically written as $a + bi$, where " a " represents the real component and " bi " the imaginary component, with " i " defined as the square root of -1 . These numbers extend the real number system and allow for solutions to equations that do not have real roots. Dividing complex numbers involves more than simple arithmetic; it requires a systematic approach to eliminate the imaginary unit from the denominator, ensuring the result is expressed in standard form.

Definition and Components of Complex Numbers

The real part " a " and the imaginary part " b " are real numbers, and the imaginary unit " i " satisfies $i^2 = -1$. Complex numbers can be represented on the complex plane, with the horizontal axis indicating the real part and the vertical axis indicating the imaginary part. This geometric interpretation aids in understanding operations such as addition, subtraction, multiplication, and division.

The Need for Division in Complex Numbers

Division of complex numbers arises in various mathematical and applied contexts, including signal processing, control theory, and electrical engineering. It is essential to perform division accurately to simplify expressions, solve equations, and analyze systems involving complex quantities.

Key Techniques for Dividing Complex Numbers

Dividing complex numbers relies on the concept of the complex conjugate to rationalize the denominator. The conjugate of a complex number $a + bi$ is $a - bi$. Multiplying the numerator and denominator of a complex fraction by the conjugate of the denominator removes the imaginary unit from the denominator, resulting in a real denominator.

Using the Complex Conjugate

The primary step in dividing complex numbers is to multiply both the numerator and denominator by the conjugate of the denominator. This process transforms the denominator into a real number, typically the sum of the squares of the real and imaginary parts of the original denominator, facilitating straightforward division.

Step-by-Step Division Process

1. Identify the complex numbers in the form $(a + bi) \div (c + di)$.
2. Find the conjugate of the denominator: $(c - di)$.
3. Multiply numerator and denominator by the conjugate: $[(a + bi)(c - di)] \div [(c + di)(c - di)]$.
4. Expand both products using distributive property or FOIL method.
5. Simplify the denominator by using the fact that $i^2 = -1$.
6. Separate the real and imaginary parts in the numerator.
7. Divide both parts by the real denominator to express the result in standard form.

Sample Problems and Solutions

Examples are an integral part of any divide complex numbers worksheet. Below are sample problems demonstrating the division process, accompanied by detailed solutions to illustrate each step clearly.

Problem 1: Divide $(3 + 4i)$ by $(1 - 2i)$

Step 1: Identify numerator and denominator: $(3 + 4i) \div (1 - 2i)$.

Step 2: Find the conjugate of the denominator: $(1 + 2i)$.

Step 3: Multiply numerator and denominator by the conjugate:

$$[(3 + 4i)(1 + 2i)] \div [(1 - 2i)(1 + 2i)].$$

Step 4: Expand numerator: $3(1) + 3(2i) + 4i(1) + 4i(2i) = 3 + 6i + 4i + 8i^2$.

Since $i^2 = -1$, $8i^2 = -8$.

Numerator simplifies to $(3 - 8) + (6i + 4i) = -5 + 10i$.

Step 5: Expand denominator: $1(1) + 1(2i) - 2i(1) - 2i(2i) = 1 + 2i - 2i - 4i^2$.

$2i - 2i$ cancel out, and $-4i^2 = 4$.

Denominator simplifies to $1 + 4 = 5$.

Step 6: Divide real and imaginary parts by denominator:

Real part: $-5 \div 5 = -1$.

Imaginary part: $10i \div 5 = 2i$.

Final answer: $-1 + 2i$.

Problem 2: Divide $(5 - 3i)$ by $(2 + i)$

Step 1: Identify numerator and denominator: $(5 - 3i) \div (2 + i)$.

Step 2: Find the conjugate of the denominator: $(2 - i)$.

Step 3: Multiply numerator and denominator by the conjugate:

$$[(5 - 3i)(2 - i)] \div [(2 + i)(2 - i)].$$

Step 4: Expand numerator: $5(2) - 5(i) - 3i(2) + 3i(i) = 10 - 5i - 6i + 3i^2$.

$$3i^2 = 3(-1) = -3.$$

Numerator simplifies to $(10 - 3) + (-5i - 6i) = 7 - 11i$.

Step 5: Expand denominator: $2(2) - 2(i) + i(2) - i(i) = 4 - 2i + 2i - i^2$.

$-2i + 2i$ cancel out, and $-i^2 = 1$.

Denominator simplifies to $4 + 1 = 5$.

Step 6: Divide real and imaginary parts by denominator:

Real part: $7 \div 5 = 1.4$.

Imaginary part: $-11i \div 5 = -2.2i$.

Final answer: $1.4 - 2.2i$.
